

# OntoGuard Headless Decision Authorization Runtime

TRACE adapter Verified  
AgenTrust marketplace

A developer who finds OntoGuard on AgenTrust sees signed authorization, exact-action identity, an execution receipt, an authorized-intent reference, and TRACE after consequence. The adapter does not generate that authorization. It only projects proven execution into TRACE. The missing issuer is the Headless Runtime.

## COMMERCIAL CONTRACT (put this sentence in the marketplace adapter README)

*Production authorization objects consumed by this adapter are issued by OntoGuard Headless Decision Authorization Runtime or another implementation conforming to the same authorization contract.*

## Insert path — do not replace the stack

Runtime 1.0.21 is a self-contained FastAPI service. No call-home. Production authorize requires tenant corridors and resource\_id plus state\_version or resource\_version. Caller pack is never authoritative. TRACE remains post-execution only.

## Responsibility split

### Partner already owns

Agent runtime, IdP / MCP gateway, tool catalog, committing executor, evidence plane.

### Runtime owns

Signed ALLOW / BLOCK / ESCALATE on the exact proposed state transition; handoff, movement, and action-binding digests (RFC 8785 JCS).

### Marketplace adapter owns

Verify signed result + independent execution receipt; emit TRACE v0.2 Level 0 only on ALLOW\_EXECUTION\_PROVEN.

### Adapter does not own

OntoGuard core authorization. BLOCK / ESCALATE / ALLOW-without-receipt emit no TRACE.

Runtime docs: <https://ontoguard.ai/runtime> Adapter: [agenttrust-io/integrations#201](https://agenttrust-io/integrations#201) Site write-up: [ontoguard.ai/agenttrust-decision-authorization-integration.html](https://ontoguard.ai/agenttrust-decision-authorization-integration.html)

# The fixture that makes the runtime necessary

Same agent. Same tool. Same identity. Same corridor. The authorized act is a \$250,000 release. A \$260,000 payload is a different act. Prior ALLOW does not bind. TRACE is not written.

## ALLOW · \$250,000

- Action: RELEASE\_PAYMENT
- PENDING → RELEASED
- commit\_count 0 → 1
- Signed ALLOW on exact binding
- Independent execution receipt
- Adapter: ALLOW\_EXECUTION\_PROVEN
- TRACE v0.2 Level 0 emitted
- references[0].rel = authorized-intent
- references[0].id = handoff\_hash

## REFUSE · \$260,000 mutation

- Same corridor, mutated amount
- State remains PENDING
- commit\_count stays 0
- No reuse of the \$250k ALLOW
- Execution refused before commit
- No valid execution receipt
- Adapter emits no TRACE record
- Not a policy rewrite — different act
- Maintainer-reproduced in review

## Trusted-context separation

The agent proposes action and intent. It does not get to declare identity, current state, resource versions, authority, evidence, or policy. Those arrive from the partner control plane (gateway, IdP, Opaque-assembled context, or customer systems). The runtime authorizes only that assembled object. TRACE is written only after an independent executor proves the same object ran.

### Agent may supply

Proposed action, intent text, parameters it wants executed.

### Partner must supply

Identity, tool permission, resource\_id, state/resource version, authority, evidence, policy in force.

### Runtime returns

ALLOW / BLOCK / ESCALATE plus signed result bytes, handoff\_hash, movement\_hash, action\_binding\_digest.

## Production modes

embedded production: /v1/candidate-authorize allowed; /v1/authorize is 403. opaque\_external production: /v1/authorize allowed on Opaque-assembled context; candidate-authorize is 403. Both call the same private \_authorize\_trusted(). Full semantic provider stays inside Opaque. Marketplace adapter is the public TRACE path.

## ASK

One write-path already in the partner gateway. Same identity, same tool, two payloads. Runtime issues the signed object. Executor honors BLOCK. Adapter writes TRACE only on the \$250k path. That is the OEM motion. Not a platform tour.
